

Every customer count in the plan is **typed once**

New logos are typed by size band and by year. Everything downstream, every dollar of revenue, cost and cash, is calculated from them. A reader who disagrees with the customer count can change it and watch the whole plan move, which is the point of building it this way.

1 New logos, by tier and by year

Tier	2027	2028	2029	2030	2031	Five year
Command and institution	0	0	1	2	3	6
Enterprise and complex	2	6	10	12	14	44
Mid market regulated	8	24	44	46	52	174
Small regulated firm	55	148	196	146	166	711
Partner and white label	4	6	8	8	9	35
New logos in the year	69	184	259	214	244	970

Legend. These are the only customer figures typed anywhere in the workbook. 2026 carries none, because the two design partners are not paid subscriptions. The largest year is 2029 at 259 signatures, which is the year the outside review wave converts.

970 signatures, 835 customers.

The gap is churn. Losses come off the opening base before each year's joiners are added, so the plan has to sign 970 firms to be holding 835 at the end of 2031.

The closing base, after the leavers

Opening customers, less those who left, plus those who joined. No total is typed anywhere.

Tier	Churn a year	2027	2028	2029	2030	2031
Command and institution	3%	0	0	1	3	6
Enterprise and complex	5%	2	8	18	29	41
Mid market regulated	8%	8	31	73	113	156
Small regulated firm	7%	55	199	381	501	631
Partner and white label	8%	4	10	17	24	31
End customers, excluding partners		65	238	473	645	835
Average customers billed in the year		32	152	355	559	740

Legend. Churn is applied to the opening base before the year’s new logos land, and it is set per tier rather than blended: three per cent at the top, where one customer is a bank, and eight at the widest. The billed line is the average of opening and closing, which is the half year convention the revenue lines are calculated on.

2 Where the base sits at the end of the plan

Bars start at zero and run to 631. Three quarters of the customers sit in the smallest tier, which carries a fifth of the revenue. The command tier is six customers, and the first of them does not sign until 2029.

The share of the tier the plan actually takes is small everywhere except the top.

631 of 13,746 small firms is 4.6 per cent. 156 of 3,091 mid market firms is 5.0 per cent. 41 of 552 enterprise firms is 7.4 per cent, and 6 of 65 institutions is 9.2 per cent. The plan needs a larger share of the tiers with the fewest firms in them, which is the opposite of how a penetration rate usually reads.

A cohort keeps the price it signed at, for as long as it stays

This is the mechanism behind every subscription figure in the plan, and it is the reason the blended price rises while the card does not move.

What a cohort is	Every customer that signed in the same year. They are carried forward together, because the price attaches to the year of signature rather than to the year of billing.
What the step is	The card rises once, on 1 January 2028. The 2027 cohort locked at 1.115 times the card. Every cohort from 2028 onwards sits at 1.25 times it. Nobody moves between those two numbers, ever.
Why the blended figure rises anyway	Because the later cohorts come to outnumber the first one. The blended step runs from 1.11 in 2027 to 1.24 by 2031, and it is a mix effect rather than a price rise.
How it is billed	On a half year convention, so a customer signing mid year is billed for half of it. That is what the average billed line in the table on the previous page carries.

3 The blended step, and the card underneath it

	2027	2028	2029	2030	2031
The card, every tier	1.00	1.00	1.00	1.00	1.00
Blended step actually realised	1.11	1.19	1.23	1.24	1.24

Legend. The card never moves and the scenario selector cannot reach it. A scenario moves volume and attachment, never price, which is why a reader can test the customer plan without also testing the price plan.

The price is a go to market decision, not a lever on the headline.

Because the smallest tier carries three quarters of the customers and a fifth of the money, moving its price by a fifth moves 2031 revenue by 4.7 per cent. Moving the customer count moves everything.

Can the team actually deliver the ramp

The operational bridge between the sales plan and the hiring plan, and the one place the workbook tests it.

Test	2027	2028	2029	2030	2031
Customers live at the year end	65	238	473	645	835
Implementation and customer success people	4	8	11	13	16
Customers per implementation person	16.2	29.8	43.0	49.6	52.2
Capacity ceiling per person	30	40	55	68	75
Headroom, customers	55	82	132	239	365

Legend. The ceiling rises from thirty to seventy five customers a person as setup becomes standard. Negative headroom would mean the ramp cannot be delivered by the team in the hiring plan, which is a hiring decision rather than a forecasting one. It stays positive in every year.

4 And can the sales team close it

Test	2027	2028	2029	2030	2031
New logos in the year	69	184	259	214	244
Quota carrying heads required, at 26 a head	3	8	10	9	10

Legend. An average across the bands. Small firms are sold to by phone at a higher rate and enterprise and command firms are far slower, so the average is the check rather than the plan.

The one number that cannot be modelled.

How long a new customer waits for their first signed reconciliation appears nowhere in this arithmetic, because it can only be observed. The milestone is two weeks by customer twenty. If it slips, the capacity table above is the first place it shows up, and the gross margin is the second.
